Classification of social system

Information on the social system and the occurrence of paternal care was collected during a systematic literature review where we searched for information on every non-human mammalian species (following the nomenclature of *(45)*), collecting information from the primary literature, by searching for each species latin name on Google Scholar, from encyclopedias *(46)*, and from published reviews (including *1, 4*). Our classification of species focused on the social organization, the distribution of breeding adults in the population. We classified a species as socially monogamous if the majority of breeding females (>50%) share a home-range for more than one year with one male, but no other conspecific breeders. Our focus on breeding females means that species such as *Hapalemur griseus*, where 60% of groups contain only one breeding female, were classified as social, since the majority of breeding females reside with at least one other breeding female *(47)*. Singular cooperative breeders, where non-breeding offspring provide support to the dominant pair, were classified as socially

monogamous *(29)*. We excluded species in which males guard individual females during their receptive period, but might guard several females during a breeding season/year. Species were classified as solitary if breeding females occupy independent home-ranges, even though they may share foraging grounds or sleeping places. Social interactions in solitary species are restricted to mating and interactions between mothers and offspring. Species were classified as group-living if two or more breeding females associate with each other within the same home-range or at the same breeding site and females tolerate the presence of other females, sharing all parts of their home-ranges. Species were classified as showing paternal care if males regularly contribute to feeding or carrying offspring. Like previous authors *(2, 14)*, we restricted paternal care to only include behaviour that is clearly adapted to benefit offspring, and excluded behaviour that might have benefits for the individual itself or all other group members (such as alarm-calling). We provide all data as supplement; please contact D. L. for a spreadsheet copy. While the supplement provides a single reference for each species for further information, classification of most species was based on information from several sources. Information on the occurrence of infanticide was compiled from previous reviews *(48, 49)*.

Data on ecological and life-history parameters

We compiled information on the potential correlates of social monogamy from the following reviews and databases: body mass, litters per year, and length of gestation and lactation *(50–52)*; population density and home-range size *(51)*; home-range overlap *(53)*; diet *(54)*; male tenure length *(55)*; and sexual dimorphism *(56-59)*. We provide links to all external databases in Supplementary Table S3. All continuous variables were log-transformed before analyses.

The updated mammalian supertree *(15)* was used as the basis for the phylogenetic analyses. The tree was truncated to match the species in the dataset using functions of the package 'ape' *(60)* in the statistical software R *(61),* leading to the exclusion of 255 species during the phylogenetic reconstruction. The distribution of social monogamy in mammals according to this phylogeny is illustrated in Supplementary Figure 1. We resolved polytomies randomly for all analyses that require bifurcating trees, and repeated each analysis with three independent resolutions, which in all cases gave consistent results.

A variety of approaches were used to reconstruct ancestral states for all mammalian species and for each mammalian Order. We inferred ancestral states using the multistate reconstruction in BayesTraits' Discrete and the maximum likelihood approach for discrete characters implemented in the package 'ape' in R and in Mesquite *(62)*. The reconstructed states were used to determine the ancestral social system before transitions to social monogamy. We estimated Pagel's lambda as a measure of phylogenetic signal for each social system using functions in the R-package 'geiger' *(63)*, and calculated Blomberg's K *(64)* for all three social systems combined (socially monogamous: 0, solitary: 1, group living: 2) using functions in the R-package 'picante' *(65)*.

We subsequently tested whether transitions to social monogamy were constrained to solitary species using the modules "Discrete" *(22)* and “Multistate” from the program "BayesTraits" *(17)*. In all BayesTraits analyses, likelihoods models of trait evolution were estimated based on the dated phylogeny, an ultrametric phylogeny, where all tips have the same distance to the root and branch lengths are proportional to the number of descendants *(66)*, and a phylogeny with all branch lengths set to equal one. Analyses based on trees in which all branch length were set to be equal to one produced the best likelihoods, and we present their results

below. We allowed the traits to vary their rate of evolution across the tree, and run each analysis for 50 maximum likelihood estimations. In “Discrete”, we assessed significance between dependent and independent models by comparing the likelihood ratio statistic against a chi-squared distribution with four degrees of freedom *(22)*. If results suggested that transition in one of the variables depended on the state of the other variable (e.g. transition to social monogamy only occurring from solitary ancestors), we repeated the analysis constraining the rate of transition in the dependent variable to be equal for both states of the other variable. Unconstrained models were considered to explain the data significantly better if the likelihood ratio statistic exceeded a chi-squared distribution with one degree of freedom. In “Multistate”, we compared the likelihood of an unconstrained model to the likelihood of a model that forced the transitions to social monogamy to occur equally likely from solitary and from group-living ancestors, and to a model in which we forced transitions to social monogamy to only occur from group-living ancestors.

We performed a series of different statistical analyses to investigate potential correlates of social monogamy, depending on the hypotheses and the type of data. When assessing the relationship between social monogamy and other binary traits, such as paternal care, we first compared the occurrence of the trait between solitary and socially monogamous species using Wilcoxon-tests and we regressed phylogenetic independent contrasts. Next, we assessed whether the two traits evolved independently through model comparisons in BayesTraits' Discrete. For tests where we predicted that social monogamy or paternal care might influence a continuous response variable, such as the number of litters per year, we used Anova and phylogenetic Anova in the R-package 'geiger', and phylogenetic generalized least squares regressions (pgls) using the package 'caper' *(67)*. In the pgls analyses, we estimated the degree of phylogenetic signal by

performing a maximum-likelihood estimate of Pagel's lambda. In cases where we predicted that a continuous variable, such as population density, might influence the occurrence of social monogamy, we performed Wilcoxon-tests and binomial generalized linear models. Binomial regressions were performed using MCMCglmm *(20)*, including the phylogenetic relationship betweens species as covariance matrix. In MCMCglmm, terms were considered statistically significant when the calculated pMCMC values were less than 0.05. We ran analyses initially with two different priors, either fixing the variances at 1 and covariances at 0, or using a very informative prior *(68)*. The two different priors led to highly similar estimates for the fixed terms, and we report the values from the fixed prior. Each analysis was repeated three times, and was checked for convergence using the Gelman-Rubin statistic to compare within- and between-chain variance in the R-package 'coda' *(69)*. In all cases the potential scale reduction factor was less than 1.1 *(70)*. We additionally checked the associations between the distribution of social monogamy and population density, home range size, and life history for any potential confounding effects of body mass *(4)*, even though body mass did not differ significantly between socially monogamous and solitary species in phylogenetically controlled regressions. We performed phylogenetic generalized linear squares regressions of population density and of home range size on body mass using the package 'caper' in R *(67)* to assess the effect of the residuals from these regressions on the distribution of social monogamy. In addition, we included body mass and social monogamy or paternal care as explanatory factors in regression models explaining variation in population density, home range size, and life history. None of this changed any of the results.

Supplementary Table S1: Overview of the distribution of social monogamy across mammalian Orders

Order	Species classified	Species with social monogamy	Proportion of socially monogamous species
AFROSORICIDA	11		0%
ARTIODACTYLA	187	6	3%
CARNIVORA	202	32	16%
CETACEA	54		0%
CHIROPTERA	174	10	6%
CINGULATA	14		0%
DASYUROMORPHIA	14		0%
DIDELPHIMORPHIA	13		0%
DIPROTODONTIA	15	2	13%
ERINACEOMORPHA	15		0%
HYRACOIDEA	3		0%
LAGOMORPHA	72	1	1%
MACROSCELIDEA	15	14	93%
MONOTREMATA	5		0%
NOTORYCTEMORPHIA	2		0%
PERAMELEMORPHIA	5		0%
PERISSODACTYLA	16		0%
PHOLIDOTA	8		0%
PILOSA	10		0%
PRIMATES	361	106	29%
PROBOSCIDEA	3		0%
RODENTIA	941	57	6%
SCANDENTIA	16		0%
SIRENIA	1		0%
SORICOMORPHA	384	1	0%
TUBULIDENTATA	1		0%
Total	2545	229	9%

Supplementary Table S2: Likelihood comparisons of different BayesTraits' Discrete models

We first compared models assuming a dependent evolution between the two traits under analysis to models assuming an independent evolution. If a model of dependent evolution had a significantly better likelihood, we constructed dependent models that constrained the relevant transition rate (e.g. from solitary ancestors to social monogamy). For the models investigating the association between social monogamy and male behaviour, only models assuming a dependent evolution with paternal care are supported (assuming that paternal care never evolved from an ancestor which was not socially monogamous). Because models investigating the evolution of social monogamy from solitary ancestors that included all species did not converge, we run separate analyses for each of the Orders which contain more than 10 socially monogamous species and more than 10 solitary species. For carnivores, rodents, and bats, the transition rate to social monogamy from an ancestor that is not solitary is estimated to be zero. For primates, the best model supports a dependent evolution, but suggests a very low rate of transitions to social monogamy from group living ancestors. In analyses which exlcude the genus Eulemur from the analyses, the best model suggests that social monogamy never evolved from a group-living ancestor. The most likely BayesTraits' Multistate models also suggest that social monogamy only evolved from solitary ancestors.

		Log-likelihood of a model assuming the evolution of the traits to be		
		independent	dependent and unconstrained	dependent and constrained
Evolution of social monogamy from solitary ancestors	Primates	-63.46	-54.57	-59.07
	Carnivores	-99.37	-94.92	-106.51
	Rodents	-308.45	-303.45	-312.95
	Chiroptera	-111.14	-101.10	-113.72
Evolution of paternal care in socially monogamous ancestors		-408.23	-384.58	-388.72
Evolution of social monogamy and male infanticide		-123.93	-122.43	
Evolution of social monogamy and infanticide risk		-526.46	-524.4

Supplementary Figure S1:
Phylogenetic distribution of social monogamy in four mammalian Orders

The four phylogenetic trees depict some of the distribution of solitary living, social monogamy, and group living in mammalian species, and indicate ancestral states based on a parsimonious reconstruction. Phylogenetic relationships are based on the mammalian supertree. Reconstructed ancestral states differ slightly when applying alternative techniques (e.g. ancestor of Chiroptera), but all approaches converge to indicate that social monogamy derived almost exclusively from ancestors in which individuals were solitary.

a) Carnivores

Legend: green = solitary, blue = group living, black = social monogamy

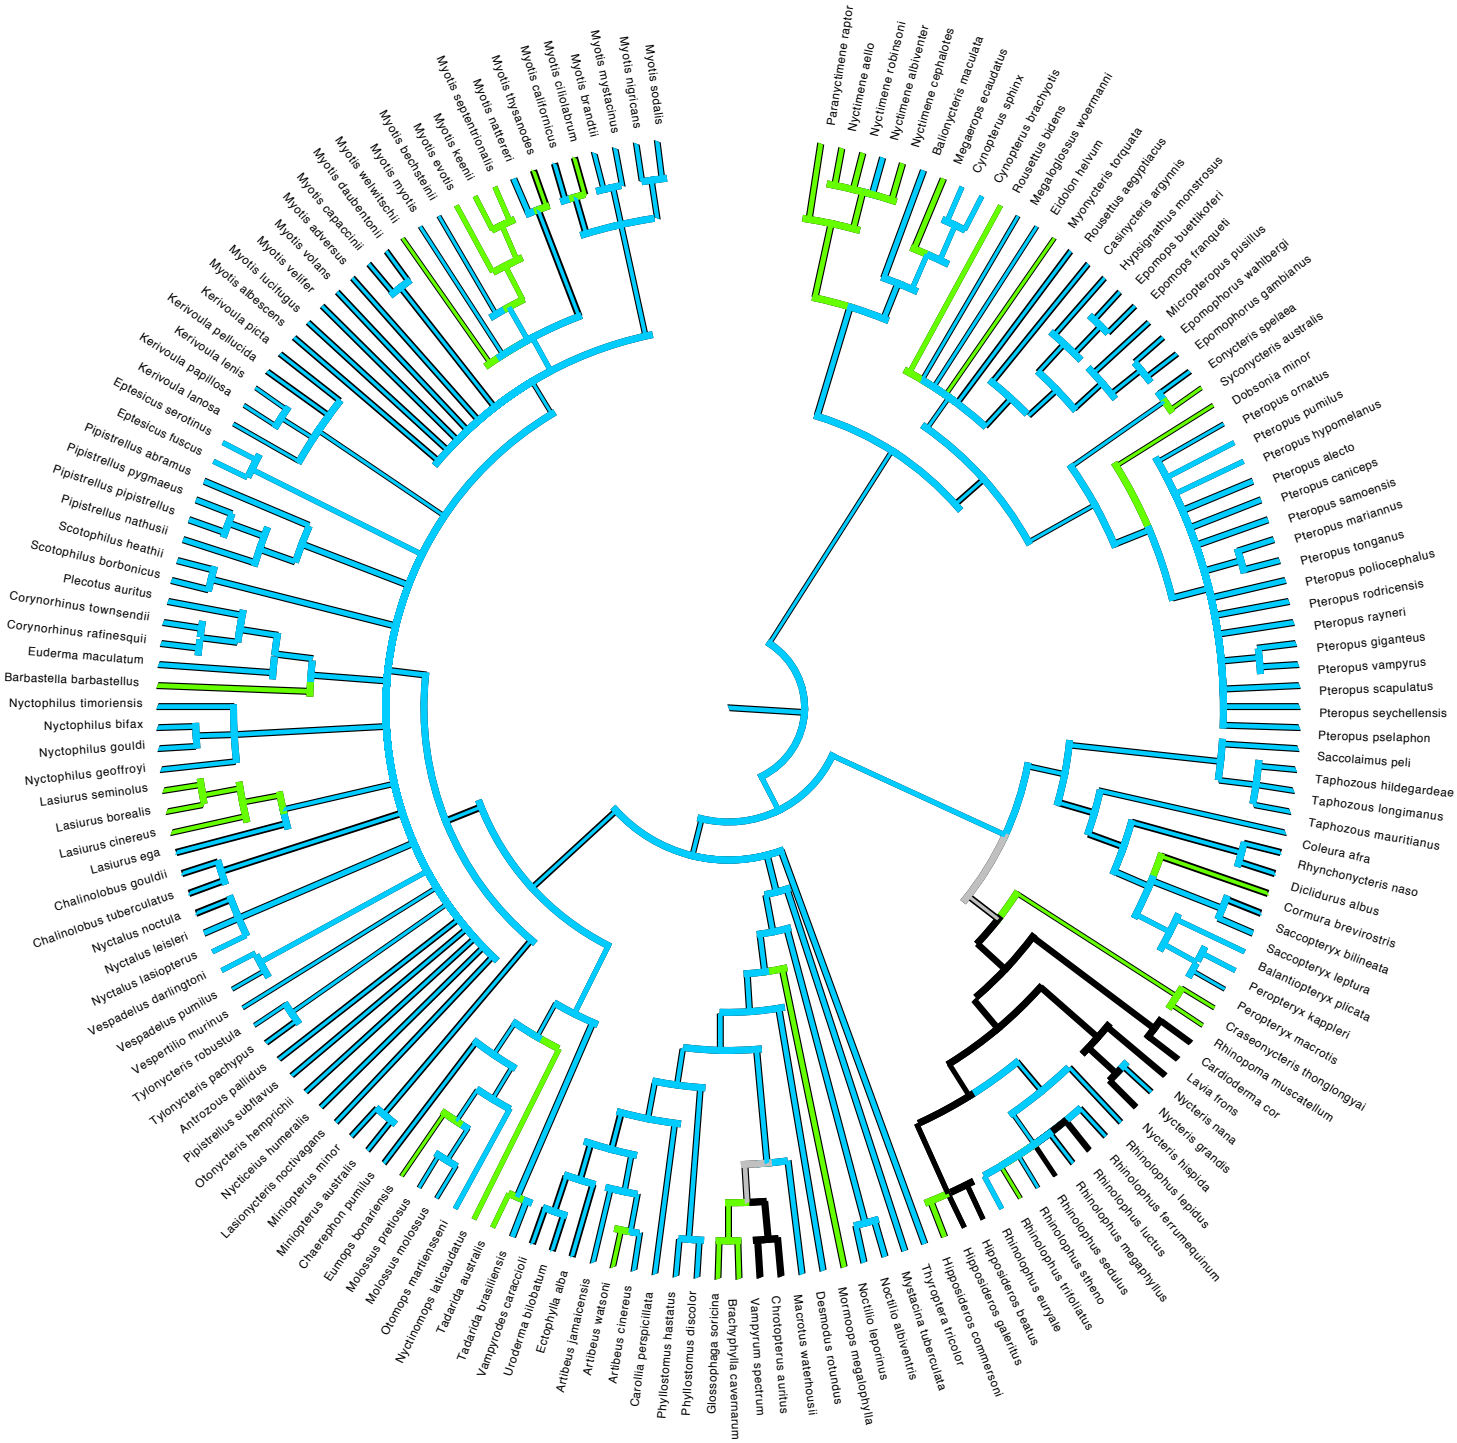

Figure is scalable, species names will become visible with higher zoom

b) Chiroptera

Legend: green = solitary, blue = group living, black = social monogamy

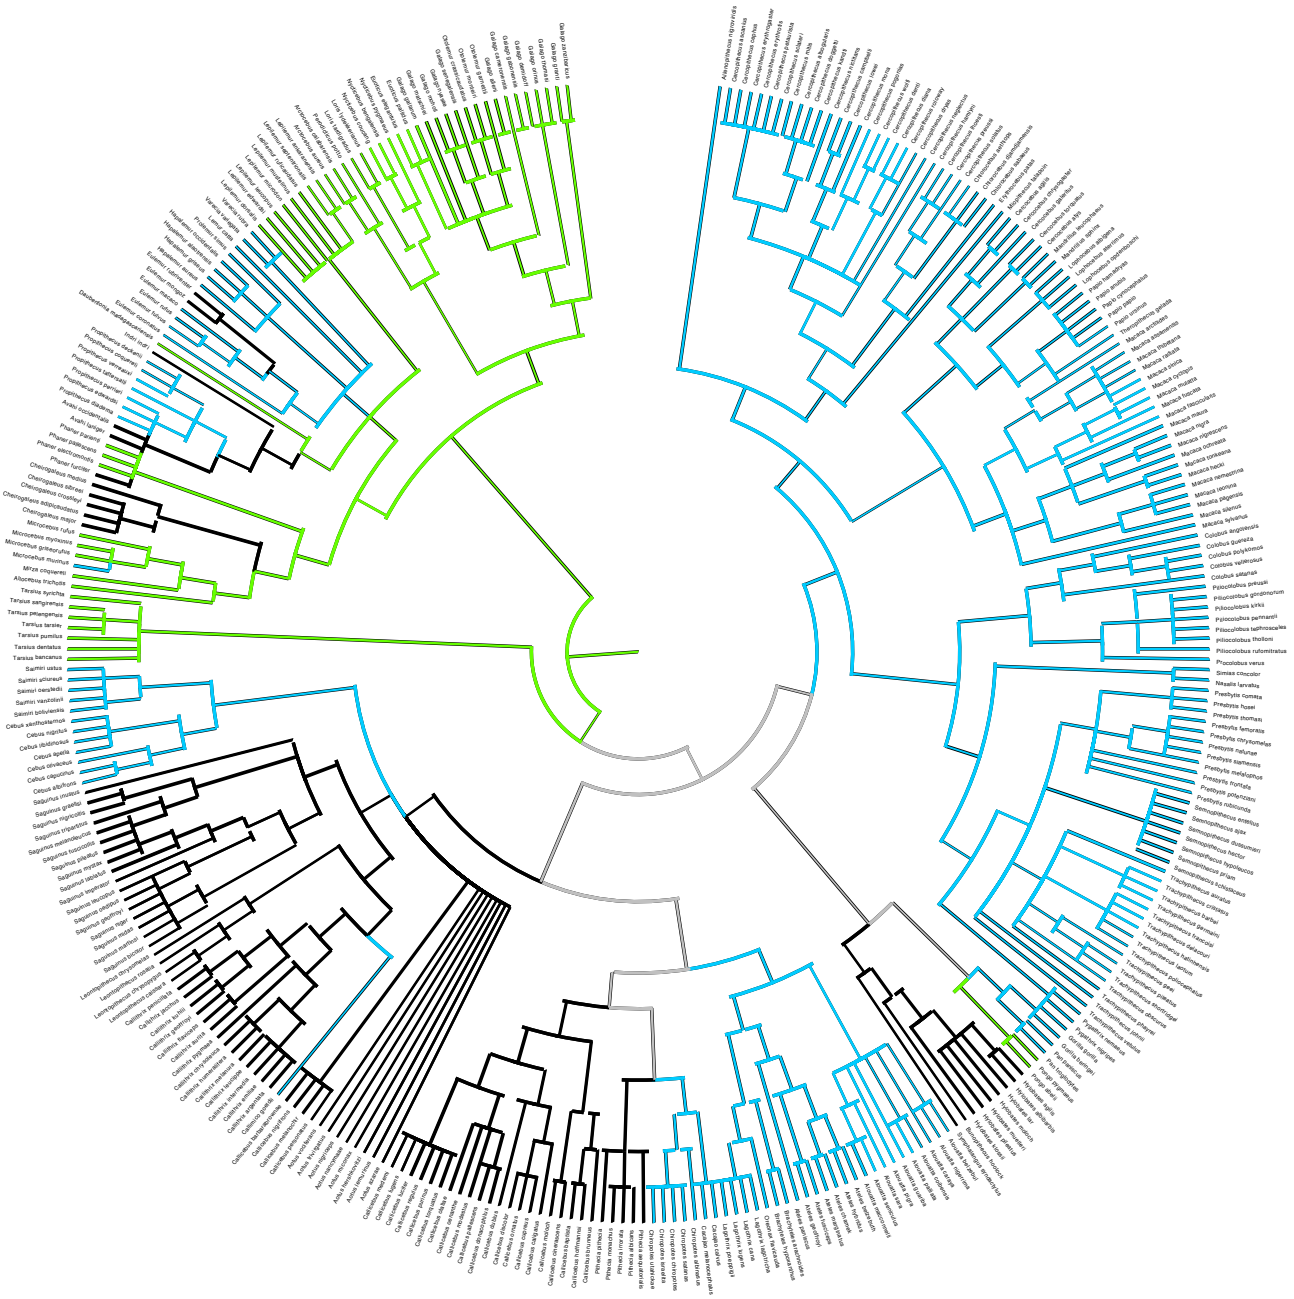

Figure is scalable, species names will become visible with higher zoom

c) Primates

Legend: green = solitary, blue = group living, black = social monogamy

Figure is scalable, species names will become visible with higher zoom

d) Rodentia

Legend: green = solitary, blue = group living, black = social monogamy

Figure is scalable, species names will become visible with higher zoom
